2 computeMemory

climate

Dataframe with palaeoclimatic data.

Description

A dataframe containing palaeoclimate data at 1 ky temporal resolution with the following columns:

Usage

data(climate)

Format

dataframe with 10 columns and 7986 rows.

Details

- age in kiloyears before present (ky BP).
- temperatureAverage average annual temperature in Celsius degrees.
- rainfallAverage average annual precipitation in milimetres per day (mm/day).
- temperatureWarmestMonth average temperature of the warmest month, in Celsius degrees.
- temperatureColdestMonth average temperature of the coldest month, in Celsius degrees.
- *oxigenIsotope* delta O18, global ratio of stable isotopes in the sea floor, see http://lorraine-lisiecki.com/stack.html for further details.

computeMemory

Quantifies ecological memory with Random Forest

Description

Takes the oputput of prepareLaggedData to fit the following model with Random Forest:

$$p_t = p_{t-1} + \dots + p_{t-n} + d_t + d_{t-1} + \dots + d_{t-n} + r$$

where:

- *d* is a driver (several drivers can be added).
- t is the time of any given value of the response p.
- t-1 is the lag number 1 (in time units).
- $p_{t-1} + ... + p_{t-n}$ represents the endogenous component of ecological memory.
- $d_{t-1} + ... + d_{t-n}$ represents the exogenous component of ecological memory.
- d_t represents the concurrent effect of the driver over the response.
- r represents a column of random values, used to test the significance of the variable importance scores returned by Random Forest.

computeMemory 3

Usage

```
computeMemory(
  lagged.data = NULL,
  drivers = NULL,
  response = "Response",
  add.random = TRUE,
  random.mode = "autocorrelated",
  repetitions = 10,
  subset.response = "none"
)
```

Arguments

lagged.data a lagged dataset resulting from prepareLaggedData. See laggedSimData as

example.

drivers a string or vector of strings with variables to be used as predictors in the model

(i.e. c("Suitability", "Driver.A"))

response character string, name of the response variable (typically, "Response_0")

add.random if TRUE, adds a random term to the model, useful to assess the significance of

the variable importance scores

random.mode either "white.noise" or "autocorrelated". See details.

repetitions integer, number of random forest models to fit

subset.response

character string with values "up", "down" or "none", triggers the subsetting of the input dataset. "up" only models memory on cases where the response's trend is positive, "down" selectes cases with negative trends, and "none" selects

all cases.

min.node.size integer, argument of the ranger function. Minimal number of samples to be

allocated in a terminal node. Default is 5.

num.trees integer, argument of the ranger function. Number of regression trees to be fitted

(size of the forest). Default is 2000.

mtry integer, argument of the ranger function. Number of variables to possibly split

at in each node. Default is 2.

drivers a character string or vector of character strings with variables to be used as

predictors in the model (i.e. c("Suitability", "Driver.A")). Important: drivers

names must not have the character "_".

Details

This function uses the ranger package to fit Random Forest models. It fits the model explained above as many times as defined in the argument repetitions. To test the statistical significance of the variable importance scores returned by random forest, on each repetition the model is fitted with a different r (random) term. If random.mode equals "autocorrelated", the random term will have a temporal autocorrelation, and if it equals "white.noise", it will be a pseudo-random sequence of numbers generated with rnorm, with no temporal autocorrelation. The importance of the random

4 computeMemory

sequence (as computed by random forest) is stored for each model run, and used as a benchmark to assess the importance of the other predictors used in the models. Importance values of other predictors that are above the median of the importance of the random term should be interpreted as non-random, and therefore, significant.

Value

A list with three 4 slots:

- memory dataframe with five columns:
 - Variable character, names and lags of the different variables used to model ecological memory.
 - median numeric, median importance across repetitions of the given Variable according to Random Forest.
 - sd numeric, standard deviation of the importance values of the given Variable across repetitions.
 - min and max numeric, percentiles 0.05 and 0.95 of importance values of the given Variable across repetitions.
- R2 vector, values of pseudo R-squared value obtained for the Random Forest model fitted on each repetition. Pseudo R-squared is the Pearson correlation between the observed and predicted data.
- prediction dataframe, with the same columns as the dataframe in the slot memory, with the median and confidence intervals of the predictions of all random forest models fitted.
- multicollinearity multicollinearity analysis on the input data performed with vif. A vif value higher than 5 indicates that the given variable is highly correlated with other variables.

plotMemory, extractMemoryFeatures

Examples

```
#loading data
data(laggedSimData)

#computing ecological memory
mem.output <- computeMemory(
  lagged.data = laggedSimData,
  drivers = "Driver.A",
  response = "Response",
  add.random = TRUE,
  random.mode = "autocorrelated",
  repetitions = 10,
  subset.response = "none"
)</pre>
```

extractMemoryFeatures Extracts ecological memory features on the output of computeMemory.

Description

It computes the following features of the ecological memory patterns returned by computeMemory:

- memory strength maximum difference in relative importance between each component (endogenous, exogenous, and concurrent) and the median of the random component. This is computed for exogenous, endogenous, and concurrent effect.
- memory length proportion of lags over which the importance of a memory component is above the median of the random component. This is only computed for endogenous and exogenous memory.
- dominance proportion of the lags above the median of the random term over which a memory component has a higher importance than the other component. This is only computed for endogenous and exogenous memory.

Usage

```
extractMemoryFeatures(
  analysis.output = NULL,
  exogenous.component = NULL,
  endogenous.component = NULL,
  sampling.subset = NULL
)
```

Arguments

memory.pattern either a list resulting from computeMemory, or a dataframe with memory patterns of several taxa generated by experimentToTable.

exogenous.component

character string, name of the variable defining the exogenous component.

endogenous.component

character string, string, name of the variable defining the endogenous component. If the data was generated by prepareLaggedData, endogenous.component would usually be "Response".

sampling.subset

only relevant when analysis.output is the result of runExperiment on outputs of the functions simulatePopulation - aggregateSimulation and toRegularTime. Character string with the name of the column of the list with the simulation outcomes.

Details

Warning: this function only works when only one exogenous component (driver) is used to define the model in computeMemory. I am planning the implementation of this analysis for more than one driver.

Value

A dataframe with 8 columns and 1 row if memory.pattern is the output of computeMemory and 13 columns and as many rows as taxa are in the input if it is the output of experimentToTable. The columns are:

- label character string to identify the taxon. It either inherits its values from experimentToTable, or sets the default ID as "1".
- *strength.endogenous* numeric in the range [0, 100], in importance units (percentage of increment in the mean squared error of the random forest model if the variable is permuted) difference between the maximum importance of the endogenous component at any lag and the median of the random component (see details in computeMemory)
- *strength.exogenous* numeric in the range [0, 100], same as above, but for the exogenous component.
- *strenght.concurrent* numeric in the range [0, 100], same as above, but for the concurrent component (driver at lag 0).
- *length.endogenous* numeric in the range [0, 100], proportion of lags over which the importance of the endogenous memory component is above the median of the random component.
- *length.exogenous* numeric in the range [0, 1], same as above but for the exogenous memory component.
- *dominance.endogenous* numeric in the range [0, 1], proportion of the lags above the median of the random term over which a the endogenous memory component has a higher importance than the exogenous component.
- dominance.exogenous, opposite as above.
- *maximum.age*, numeric. As every column after this one, only provided if memory.pattern is the output of experimentToTable. Trait of the given taxon.
- fecundity numeric, trait of the given taxon.
- niche.A.mean numeric, trait of the given taxon.
- niche.A.sd numeric, trait of the given taxon.
- sampling numeric, trait of the given taxon.

computeMemory

laggedSimData 7

laggedSimData

Lagged data generated by prepareLaggedData

Description

A dataframe resulting from the application of prepareLaggedData to the first slot of the list simulation. The order of the cases represent age. The first row contains the "older" sample, while the last row contains the "newest one". Therefore, for a lag equal to 1, any given case of the column Response_0 is aligned with the data of the row above it. The dataframe columns are:

Usage

data(laggedSimData)

Format

dataframe with 203 columns and 9900 rows.

Details

- Response_0 numeric, values of the Response (simulated pollen abundance in this case) for the lag 0 (meaning that data in this column has not been lagged). This column is used as response variable by the function computeMemory.
- *Response_1-100* numeric, time delayed values of the response for different lags (in years). Considered together these columns represent the endogenous ecological memory.
- *Driver.A_0* numeric, values of the variable Driver A for the lag 0 (no lag). This column represents the concurrent effect of the driver over the response.
- *Driver.A_1-100* numeric, time delayed values of Driver.A for different lags (in years). Considered together these columns represent the exogenous ecological memory.

Blas M. Benito <blashenito@gmail.com>

See Also

simulatePopulation, plotSimulation

8 memoryPattern

memoryPattern

Output of computeMemory

Description

List with the following slots containing the output of computeMemory.

Usage

```
data(memoryPattern)
```

Format

dataframe with 10 columns and 7986 rows.

Details

- memory dataframe with five columns:
 - Variable character, names and lags of the different variables used to model ecological memory.
 - median numeric, median importance across repetitions of the given Variable according to Random Forest.
 - sd numeric, standard deviation of the importance values of the given Variable across repetitions.
 - min and max numeric, percentiles 0.05 and 0.95 of importance values of the given Variable across repetitions.
- R2 vector, values of pseudo R-squared value obtained for the Random Forest model fitted on each repetition. Pseudo R-squared is the Pearson correlation between the observed and predicted data.
- prediction dataframe, with the same columns as the dataframe in the slot memory, with the median and confidence intervals of the predictions of all random forest models fitted.
- multicollinearity multicollinearity analysis on the input data performed with vif. A vif value higher than 5 indicates that the given variable is highly correlated with other variables.

Author(s)

mergePalaeoData 9

mergePalaeoData

Merges palaeoecological datasets with different time resolution.

Description

It merges palaeoecological datasets with different time intervals between consecutive samples into a single dataset with samples separated by regular time intervals defined by the user

Usage

```
mergePalaeoData<-function(
datasets.list = NULL,
   time.column = NULL,
   interpolation.interval = NULL
)</pre>
```

Arguments

datasets.list

 $list\ of\ data frames,\ as\ in\ datasets. \ list\ =\ list(climate\ =\ climate.\ data frame,\ pollen\ =\ pollen.\ data frame)$

The provided dataframes must have an age/time column with the same column name and the same units of time. Non-numeric columns in these dataframes are

ignored.

time.column

character string, name of the time/age column of the datasets provided in datasets.list.

interpolation.interval

temporal resolution of the output data, in the same units as the age/time columns

of the input data

Details

This function fits a loess model of the form y ~ x, where y is any column given by columns.to.interpolate and x is the column given by the time.column argument. The model is used to interpolate column y on a regular time series of intervals equal to interpolation.interval. All columns in every provided dataset go through this process to generate the final data with samples separated by regular time intervals. This function follows the same principles as toRegularTime. Non-numeric columns are ignored, and absent from the output dataframe.

Value

A dataframe with every column of the initial dataset interpolated to a regular time grid of resolution defined by interpolation.interval. Column names follow the form datasetName.columnName, so the origin of columns can be tracked.

Author(s)

10 palaeodata

See Also

```
toRegularTime
```

Examples

```
#loading data
data(pollen)
data(climate)

x <- mergePalaeoData(
    datasets.list = list(
    pollen=pollen,
        climate=climate
),
    time.column = "age",
    interpolation.interval = 0.5
)</pre>
```

palaeodata

Dataframe with sample pollen and climate data.

Description

A dataframe containing pollen and climate data interpolated at 0.1 ky temporal resolution with the following columns:

Usage

```
data(palaeodata)
```

Format

dataframe with 10 columns and 7986 rows.

Details

- age in years, at regular intervals of 100 years.
- pinus interpolated pollen counts of Pinus.
- quercus interpolated pollen counts of Quercus.
- poaceae interpolated pollen counts of Poaceae.
- artemisia interpolated pollen counts of Artemisia.
- temperatureAverage average annual temperature in Celsius degrees.
- rainfallAverage average annual precipitation in milimetres per day (mm/day).
- temperatureWarmestMonth average temperature of the warmest month, in Celsius degrees.
- temperatureColdestMonth average temperature of the coldest month, in Celsius degrees.
- *oxigenIsotope* delta O18, global ratio of stable isotopes in the sea floor, see http://lorraine-lisiecki.com/stack.html for further details.

parameters 11

Author(s)

Blas M. Benito <blasbenito@gmail.com>

parameters

Parameters of 2 virtual taxa.

Description

A dataframe with 2 rows and 16 columns with the parameters of two virtual taxa. It was generated by parametersDataframe and fixParametersTypes. It is meant to be used as input for simulatePopulation. It's columns are:

Usage

data(drivers)

Format

numeric vector of length 10000.

Details

- label: to store names (character string) of the virtual taxa.
- maximum.age: integer, maximum possible age of the individuals in years.
- reproductive.age: integer, age of sexual maturity in years.
- fecundity: integer, number of maximum viable seeds produced by a mature individual under fully suitable conditions.
- growth.rate: numeric, parameter of the logistic growth function.
- pollen.control: numeric in the interval [0, 1]. If 0, pollen productivity depends on environmental suitability only. The larger the number, biomass takes over environmental suitability in determining pollen productivity.
- maximum.biomass: integer, maximum biomass of the individuals.
- carrying.capacity: integer, maximum sum of biomass of the individuals. Very large carrying capacities plus a low maximum.biomass generates too many individuals for the simulation to remain efficient. Try to set carrying.capacity and maximum.biomass to carrying.capacity divided by biomass returns a number lower than 1000 (and even better if it is closer to 100).
- driver.A.weight: numeric in the interval [0, 1], represents the relative influence of the driver on environmental suitability.
- driver.B.weight: numeric in the interval [0, 1], represents the relative influence of the driver on environmental suitability. The sum of weights of drivers A and B should be 1.
- niche.A.mean: numeric, in the same units as driver A. It is the mean of the normal function defining the response of the virtual taxa to driver A.
- niche.A.sd: numeric, in the same units as driver A. It is the standard deviation of the normal function defining the response of the virtual taxa to driver A.

12 plotMemory

- niche.B.mean: as above, but for driver B.
- niche.B.sd: as above, but for driver B.
- autocorrelation.length.A: numeric, only useful if several drivers generated with different autocorrelation lengths are available (and identified by the column autocorrelation.length) in the drivers argument provided to the simulatePopulation function.
- autocorrelation.length.B: same as above.

plotMemory

Plots output of computeMemory

Usage

```
plotMemory(
  memory.output = NULL,
  title = "Ecological memory pattern",
  legend.position = "right"
)
```

Arguments

memory.output a dataframe with one time series per column.

title character string, name of the numeric column to be used as response in the

model.

legend.position

character vector, names of the numeric columns to be used as predictors in the

model.

filename character string, name of output pdf file. If NULL or empty, no pdf is produced.

It shouldn't include the extension of the output file.

Value

A ggplot object.

Author(s)

pollen 13

```

pollen

Dataframe with pollen counts.

Description

A dataframe with the following columns:

Usage

```
data(pollen)
```

Format

dataframe with 10 columns and 7986 rows.

Details

- age in kiloyears before present (ky BP).
- pinus pollen counts of Pinus.
- quercus pollen counts of Quercus.
- poaceae pollen counts of Poaceae.
- artemisia pollen counts of Artemisia.

Author(s)

14 prepareLaggedData

prepareLaggedData

Organizes time series data into lags.

Description

Takes a multivariate time series, where at least one variable is meant to be used as a response while the others are meant to be used as predictors in a model, and organizes it in to quantify ecological memory through models of the form: $p_t p_{t-1} + ... + p_{t-n} + d_t + d_{t-1} + ... + d_{t-n}$

where:

- d is a driver (several drivers can be added).
- t is the time of any given value of the response p.
- t-1 is the lag number 1 (in time units).
- $p_{t-1} + ... + p_{t-n}$ represents the endogenous component of ecological memory.
- $d_{t-1} + ... + d_{t-n}$ represents the exogenous component of ecological memory.
- d_t represents the concurrent effect of the driver over the response.

Usage

```
prepareLaggedData(
  input.data = NULL,
  response = NULL,
  drivers = NULL,
  time = NULL,
  oldest.sample = "first",
  lags = seq(0, 200, by=20),
  time.zoom=NULL,
  scale=FALSE
)
```

Arguments

input.data a dataframe with one time series per column.

response character string, name of the numeric column to be used as response in the

model.

drivers character vector, names of the numeric columns to be used as predictors in the

model.

time character vector, name of the numeric column with the time/age.

oldest.sample character string, either "first" or "last". When "first", the first row taken as the

oldest case of the time series and the last row is taken as the newest case, so ecological memory flows from the first to the last row of input.data. When "last", the last row is taken as the oldest sample, and this is the mode that should be used when input.data represents a palaeoecological dataset. Default behavior

is "first".

prepareLaggedData 15

lags	numeric vector of positive integers, lags to be used in the equation. Generally, a regular sequence of numbers, in the same units as time. The use seq to define it is highly recommended. If 0 is absent from lags, it is added automatically to allow the consideration of a concurrent effect. Lags should take into account the temporal resolution of the data, and be aligned to it. For example, if the interval between consecutive samples is 100 years, lags should be something like 0, 100, 200, 300. Lags can also be multiples of the time resolution, such as 0, 200, 400, 600 (in the case time resolution is 100 years).
time.zoom	numeric vector of two numbers of the time column used to subset the data if desired. $\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \$
scale	boolean, if TRUE, applies the scale function to normalize the data. Required if the lagged data is going to be used to fit linear models.

Details

The function interprets the time column as an index representing the

Value

A dataframe with columns representing time-delayed values of the drivers and the response. Column names have the lag number as a suffix. The response variable is identified in the output as "Response_0".

   drivers = "Driver",
   time = "Time",
   oldest.sample = "first",
   lags = seq(0, 200, by=20),
   time.zoom=NULL,
   scale=FALSE
)</pre>
```

16 simulation

simulation

List with two simulation outputs.

Description

A list of dataframes with two slots, output of simulatePopulation. Each slot corresponds to a virtual taxon from the parameters dataframe. Each dataframe has the following columns:

Usage

data(simulation)

Format

numeric vector of length 10000.

Details

- Time integer, ages in years. Negative ages indicate the burn-in period.
- Pollen numeric, pollen counts
- Population.mature numeric, number of mature individuals.
- Population.immatre numeric, number of immature individuals.
- Population.viable.seeds numeric, number of viable seeds generated each year.
- *Suitability* numeric, environmental suitability computed from the driver by the normal function/s defining the taxon niche.
- Biomass.total numeric, overall biomass of the population.
- Biomass.mature numeric, sum of biomass of mature individuals.
- Biomass.immature numeric, sum of biomass of immature individuals.
- Mortality.mature numeric, number of mature individuals dead each year.
- Mortality.immature numeric, same as above for immature individuals.
- Driver.A numeric, values of driver A.
- Driver.B numeric, values of driver B, if available, and NA otherwise.
- Period qualitative, with value "Burn-in" for burn-in period, and "Simulation" otherwise.

simulatePopulation, plotSimulation

toRegularTime 17

toRegularTime

Reinterpolates aggregated simulations into regular time.

Description

Takes the output of aggregateSimulation, and interpolates it into a regular time grid.

Usage

```
toRegularTime(
    x,
    time.column="Time",
    interpolation.interval,
    columns.to.interpolate=c("Suitability", "Driver.A", "Pollen")
)
```

Arguments

```
list of dataframes (generally the output of aggregateSimulation) or single dataframe with irregular time series.

time.column character string, default value is "Time".

interpolation.interval integer, in years, time length encompassed by each sample.

columns.to.interpolate character string or character vector, columns of simulation output to be interpolated. Any subset of: "Pollen", "Population.mature", "Population.immature", "Population.viable.seeds", "Suitability", "Biomass.total", "Biomass.mature", "Biomass.immature", "Mortality.mature", "Mortality.immature", "Driver.A", "Driver.B".
```

Details

This function fits a loess model of the form $y \sim x$, where y is any column given by columns.to.interpolate and x is the column given by the time.column argument. The model is used to interpolate column y on a regular time series of intervals equal to interpolation.interval. If x is a matrix-like list returned by aggregateSimulation (on results of simulateAccumulationRate and simulatePopulation), the first column of the matrix will already have a regular time column, and therefore nothing will be done with this column of the list.

Value

If x is a list of dataframes, the function returns a list with the same structure as the input list. If x is a dataframe, the function returns a dataframe. In any case, output dataframes have the columns "Time" (now regular), and any column listed in columns.to.interpolate.
